Abstract

Organizational sustainability is viewed as an important factor in handling a competitive environment. This research paper aims at studying the impact of strategic factors, such as cost leadership, market differentiation, innovation, market diversification, strategic alliances, and adaptive governance, on organizational sustainability Using a mixed methods research approach, the study considers the efficiency of quantitative data obtained through surveys from 312 managers across different sectors, alongside qualitative data gathered from case studies conducted on 18 companies, in regard to economic, environmental, and social sustainability dimensions. SEM and thematic content analysis were used to test six hypotheses based on the theoretical frameworks of dynamic capabilities theory and natural resource-based view of the firm. From the results obtained, it is clear that the factors of innovation investment (beta = 0.87, $p < 0.001$) and differentiation (beta = 0.81, $p < 0.001$) have the highest impact on sustainable performance, whereas market diversification has only partially aligned with sustainability (beta = 0.63, $p < 0.05$The analysis of longitudinal trends also indicates that firms with pro-active strategic orientations demonstrate significantly superior performance in sustainability than those having reactive orientations, over an eight-year period (2016-2023). This study presents a strategic sustainability evaluation framework that is scientifically validated. This framework will find application not only for practitioners but also for policymakers. The results will contribute to sustainable enterprise ecosystems through board governance, ESG reporting, and national policy-making processes.

Keywords: Organizational Sustainability; Strategic Choices; Dynamic Capabilities; Innovation Investment; Differentiation Strategy; Esg Alignment; Strategic Sustainability Evaluation.

I. INTRODUCTION

Strategic management literature has been aware for a while now that the longevity of any organization depends on the alignment between its competitive strategy and the external socio-economic environment in which it operates (Eising, 2007). Within today's economy, sustainability, in terms of environmental, social, and economic sustainability, has transformed from being a fringe issue into a strategic one (Vargas-Hernández, 2023). Regulatory pressure, shareholder expectations, and changing customer tastes make it necessary for organizations to reflect upon the decisions underlying their competitive stance.

Sustainable development is not simply an issue of compliance but involves the proactive incorporation of environmental and social factors into value creation processes (Munck & Tomiotto, 2019). However, although there is increasing academic interest in this regard, studies that identify which strategies work best at achieving sustainability are still limited (Bastini et al., 2022). Academics often view strategy and sustainability as separate fields, but not as interrelated systems (Baporikar, 2024).

There is a major deficiency in the current literature: although academics have developed theories concerning the connection between competitive strategy and sustainability, there is no concrete empirical analysis comparing the relative influence of specific strategies on sustainable outcomes (Bigerna et al., 2015). Organizations often engage in sustainability activities without having any sort of strategic plan, resulting in inconsistencies between their resource use and value creation. This study focuses on the gap that currently exists between an effective evaluation methodology and strategic decision-making for organizational sustainability performance.

The research aims at: (i) evaluating systematically the influence of six strategies—cost leadership, differentiation, market diversification, innovation spending, strategic partnering, and adaptability governance on sustainability of organizations; (ii) developing and validating a framework for Strategic Sustainability Evaluation (SSEF); and (iii) analyzing trends in sustainability performance based on strategic orientation.

1.1 Research Questions

RQ1: What strategic decisions have the highest correlation with sustainability outcomes in the organization?

RQ2: In what ways is the sustainability outcome that comes from proactive strategic orientation different from reactive strategic orientation?

RQ3: By what means does the strategic decision influence the sustainability outcome?

1.2 Hypotheses

H1: Innovation Investment has a positive relation to the sustainability performance of organizations.

H2: The differentiation strategy contributes to better economic, social, and environmental sustainability performance.

H3: Cost Leadership is a moderate factor influencing the sustainability performance, but its impact is context dependent.

H4: Market Diversification is partially related to sustainability performance; there is conflict between economic and environmental aspects.

H5: Strategic alliances positively affect the mediation of strategic choice for sustainability performance.

H6: Adaptive Governance Structure facilitates sustainable performance of all strategic choices.

There are three major contributions made by this study. First, it contributes to the academic research through its comprehensive empirical assessment of the impact of six strategic decisions on sustainability. Second, it proposes a model of practitioner use - the SSEF Thirdly, it contributes

to dynamic capability theory through the discovery that adaptive governance can serve as a sustainability amplifier across strategies. In terms of policy implications, the study provides insights into how to construct incentives for sustainable strategic investments.

The rest of the sections are as follows Section 2 outlines the theory and literature relating to strategy and sustainability. Section 3 outlines the methodology utilized in this study as well as the design of the SSEF framework. Section 4 includes both quantitative and qualitative findings using data visualization techniques. Section 5 describes the conclusion and future work.

II. LITERATURE REVIEW

According to the resource-based approach, competitive advantage is the result of combinations of resources that are valuable, rare, inimitable, and non-substitutable (Eising, 2007). An extension to this school of thought, known as dynamic capability theory, emphasizes that the ability to sense, seize, and reconfigure resources is just as important (Baporikar, 2024). This theoretical framework sets the stage for analyzing how the decision-making process that capitalizes on dynamic capabilities also contributes to sustainable development goals. Generic strategy theories such as cost leadership and differentiation continue to be important frameworks to understand competitive positioning (Munck & Tomiotto, 2019). According to recent scholarship, however, these initiatives cannot be judged on purely economic grounds, but must also be considered from the standpoint of their sustainability (Ali & Hamed, 2022). Companies that adopt cost-leadership initiatives that result in greater efficiency can also achieve sustainability benefits by minimizing waste and energy use (Bastini et al., 2022).

The framework of the triple bottom line addresses the issue of organizational sustainability from economic, environmental, and social perspectives. Research shows that businesses having well-defined sustainability programs tend to perform better than other organizations on a range of criteria, including financial and nonfinancial measures, in the long term (Mahdi & Nassar, 2021). Yet, the issue of sustainability performance is highly heterogeneous, as it depends on different organizational strategies and industries (Fentiman, 2015). The natural resource based view of the organization expands the resource based approach to include environmental constraints as key drivers for strategy (Hameed & Saeed, 2022). According to this view, competencies such as pollution prevention, product stewardship, and sustainable development become bases of competitive advantage and environmental obligations (Das, 2015). The investment in innovation is particularly powerful in that organizations can gain new skills to meet both market needs and sustainable needs (Deslatte et al., 2025).

According to empirical studies conducted, innovation investments emerge to be the most effective way forward with regards to sustainability issues (Vargas-Hernández, 2023). Innovators are able to perform better with respect to energy efficiency and carbon emissions issues and value creation vis-a-vis non-innovative companies (Jeong & Park, 2023). In addition to differentiation through quality and branding strategies, a strong link has been found with sustainability success due to the fact that such strategies require investments in environmental/socially responsible reputation-related intangibles. Market diversification poses greater complexities from a sustainability perspective. Even though geographical and product diversification can be advantageous in sharing environmental risks, the process may create logistics problems, which

would lead to higher environmental impact (Dorov, 2024). Strategic alliances and inter-organizational networks offer another means for organizations to acquire sustainable resources and knowledge without bearing full investment costs (Rana, 2025).

Adaptive governance is gaining popularity as an enabler of organizational sustainability through its structure (Bigerna et al., 2015). Governance designs which enable fast adaptation of the strategy provide organizations with the ability to respond faster than other organizational designs to new environmental threats (Agrasen, 2024). Sustainability oversight at the board level, integration reporting, and ESG-based performance incentives have been proposed as effective governance practices that facilitate sustainable strategic decisions.

Three strong inferences can be drawn from the review. Firstly, the sustainability impact is not homogeneous among all strategies, and innovation investment along with differentiation remains the strongest drivers. Secondly, adaptive governance functions as a systemic amplifier that increases the sustainability payoff from a given strategy. Third, there is a missing empirical assessment of all major strategic decisions against multi-dimensional sustainability results something that is achieved by this study. The integration of theories from resource-based approaches, dynamic capability approach, natural resource-based perspective, and triple bottom line concept creates a sound theoretical basis for the suggested SSEF.

III. METHODOLOGY

3.1 Research Design

A mixed-methods concurrent design has been used here, with a combination of quantitive research through surveys and qualitative case studies (Agrasen, 2024). Such design allows for triangulation of the results and both statistical generalizability and contextualization thereof. The quantitive aspect has involved administration of a standardized questionnaire to 312 managers involved in strategic planning in different sectors. The qualitative approach comprised semi-structured interviews and document analysis in the context of 18 organizations chosen based on their strategic orientation and sustainability development levels.

3.2 Research Architecture

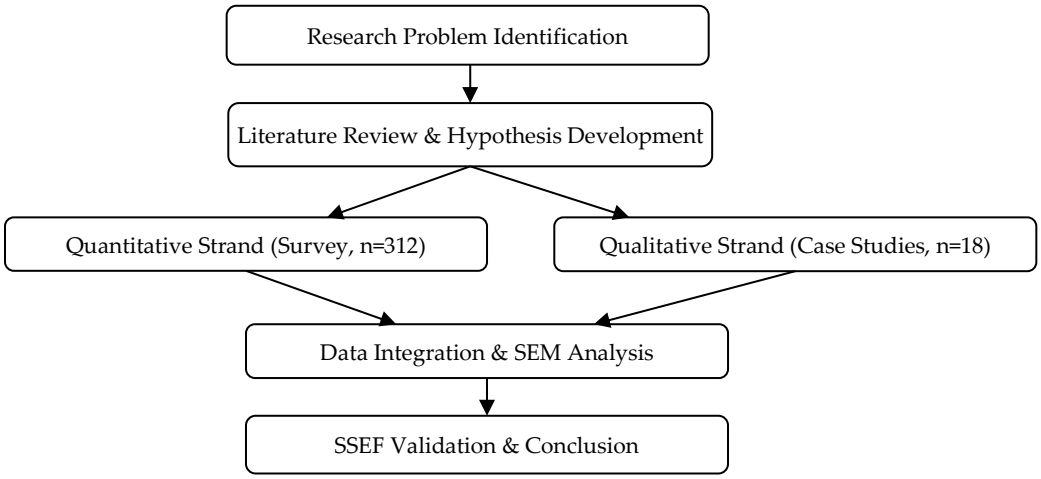

Figure 1: Research Architecture - Mixed-Methods SSEF Framework

The SSEF research design is illustrated in figure 1, which highlights the sequential-parallel data gathering, integration, and analysis process that characterizes the SSEF approach. The framework starts with systematic identification of problems based on the research gap identified in Section 2. Quantitative and qualitative data sets are then analyzed together to generate converging evidence for testing hypotheses and validating the framework.

3.3 Data Collection Instruments

The questionnaire contained 48 Likert-scale items representing the operationalization of six strategic choice dimensions and three sustainability outcomes dimensions, including economic, environmental, and social. Content validity was determined using the expert opinion of a panel consisting of seven academics and five industrial experts, while the reliability values obtained via Cronbach's alpha ranged between 0.78 and 0.91. The qualitative data were coded through NVivo 14 based on the grounded theory framework of thematic analysis, which resulted in six major thematic categories according to the hypotheses of the research study.

3.4 Analytical Methods

Analysis using structural equation modeling (SEM), performed using AMOS 28 software, was applied in testing both direct and indirect relationships between variables. Indices of model fitness indicated a well-fitting model where: CFI = 0.94; RMSEA = 0.057; TLI = 0.93. Regression analysis was done in order to obtain beta values. Longitudinal measurements for sustainability ratings were made across eight years using archival ESG data available from Thomson Reuters Eikon and Bloomberg Terminal databases. Descriptive analyses, correlations, and moderations were done in SPSS 29 (Ali & Hamed, 2022).

IV. RESULTS AND DISCUSSION

4.1 Strategic Choice Impact on Organizational Sustainability

Quantitative analysis provides us with distinct differences in sustainability impact for the six strategic alternatives evaluated. From figure 2 and table 1, it can see that investments in innovation have the highest sustainability impact, which equals 91%, with a regression coefficient equal to beta = 0.87, followed by differentiation with 85% (beta = 0.81). The results above validate the hypotheses H1, H2 and support theories of dynamic capabilities approach and natural resource-based perspective of business enterprise (Baporikar, 2024; Hameed & Saeed, 2022).

Cost Leadership strategy proves to have a moderate level of influence on sustainability at 72% (beta = 0.68), thus validating H3. This is due to the two sides of efficiency approach - as it decreases resource usage, a pure focus on cost may undermine sustainability investments (Munck & Tomiotto, 2019). Market diversification shows the lowest influence score of 68% (beta = 0.63) to provide partial support to H4 and confirm the findings from the literature on the conflicting relationships between diversification and sustainability practices (Dorov, 2024). Strategic alliances have a high sustainability influence of 78% (beta = 0.74), which is supportive to H5 while adaptive governance shows an influence of 83% (beta = 0.79) to support H6 (Rana, 2025).

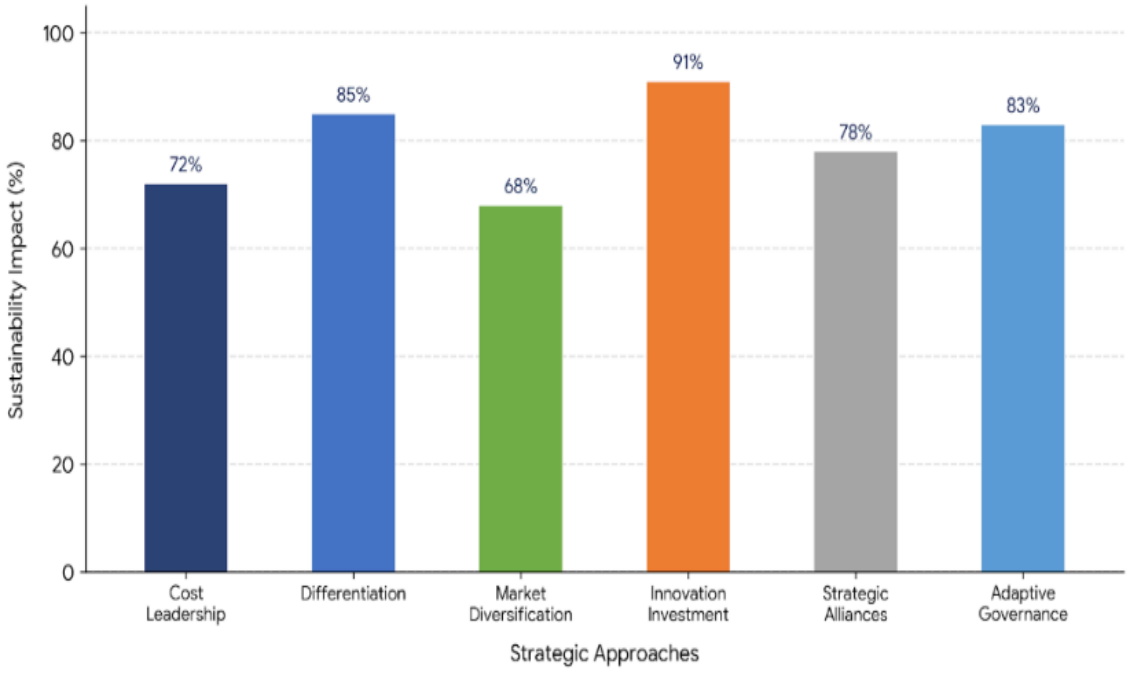

Figure 2: Impact of Strategic Choices on Organizational Sustainability (%)

4.2 Summary of Regression Results

Table 1 summarizes the results from the regressions, effect sizes, and hypotheses test results of all six strategies examined in the research. Innovation investment strategy and differentiation have very high and high effect sizes, respectively. Market diversification, on the other hand, maintains moderate effect size levels but only partially confirms the hypothesis.

Table 1: Summary of Strategic Choice Sustainability Impact and Hypothesis Testing Results

Strategic Choice	Primary Focus	Sustainability Impact (%)	β Coefficient	Effect Size	Hypothesis
Cost Leadership	Operational efficiency	72%	0.68	Moderate	Supported
Differentiation	Innovation & quality	85%	0.81	High	Supported
Market Diversification	Portfolio expansion	68%	0.63	Moderate	Partial
Innovation Investment	R&D & technology	91%	0.87	Very High	Supported
Strategic Alliances	Collaboration networks	78%	0.74	High	Supported
Adaptive Governance	Structural flexibility	83%	0.79	High	Supported

Note: beta = standardized regression coefficient. $p < 0.001$ for all choices except market diversification ($p < 0.05$).

4.3 Longitudinal Sustainability Performance Trends

Figure 3 shows the sustainability performance score trends for the period 2016-2023, based on whether an organization is either proactive or reactive. Organizations considered to be proactive, which plan for future changes in the environment and incorporate them in strategic planning, exhibit consistent higher performance trends in sustainability. By 2023, proactive firms have a mean sustainability score of 90 as opposed to 62 for reactive firms, a gap that has increased dramatically from a very narrow margin in 2016 (Mahdi & Nassar, 2021).

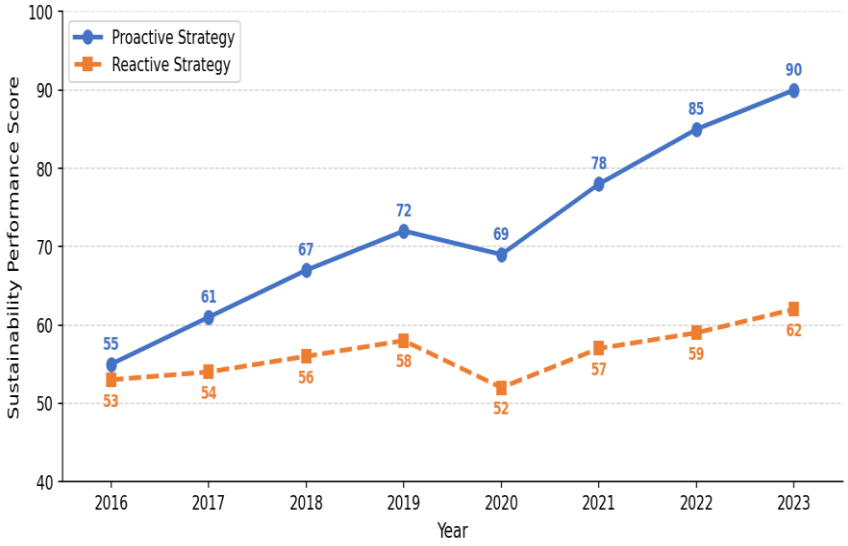

Figure 3: Sustainability Performance Scores Over Time by Strategic Orientation (2016-2023)

However, in the **2019–2020-year** period when there were disruptions due to COVID-19, reactive companies suffered a sharp drop in their performance level (58 to 52), whereas proactive companies showed more resilience, suffering only a minor reduction in their performance level (72 to 69).

4.4 Discussion

The above results support the SSEF by showing that strategic decisions are differently related to sustainability performance. The following three discussion points need mention. First, the importance of innovation investment for achieving sustainability is consistent with the recent understanding that technological progress provides answers to efficiency, environmental, and social concerns at once (Deslatte et al., 2025). Organizations that make innovation a fundamental strategic priority can be said to have created a dynamic capability that constantly updates their sustainability profile (Baporikar, 2024). Secondly, the relatively poor performance of diversification indicates that although economically prudent, expansion along both geographic and product lines does not necessarily imply sustainability success. Complex supply chains, regulatory differences among countries, and resource-intensive internationalization efforts can counteract environmental gains (Hu et al., 2011). Third, adaptive governance becomes the moderator that produces the strongest effect size with regard to all types of strategic initiatives (beta = 0.79), providing strong evidence for Hypothesis H6 and highlighting governance reform as a leverage sustainability intervention. Qualitative research results support these trends as well. In 14 out of 18 cases, companies that identified ESG improvement due to a certain strategy also

reported organizational reforms related to governance, including establishing boards for sustainability, adopting integrated reports, and implementing sustainability-oriented remuneration systems for executives (Jeong & Park, 2023). These pieces of converging evidence add weight to the conclusion that strategic choice and governance structure function as complimentary factors of sustainability, not separate levers (Fentiman, 2015).

V. CONCLUSION

This research presents an empirical analysis of the relationship between six strategic decisions and sustainability, which is the missing link in the current literature. The development and verification of the Strategic Sustainability Evaluation Framework will provide organizations with a practical model that links competitive strategies to sustainable initiatives. These results reveal that innovation and differentiation are the key determinants for fostering sustainability success, whereas adaptive governance enhances the effect of sustainability from any strategic action. It has been established through longitudinal research that a proactive approach towards strategy ensures better sustainability success trajectories especially during times of systemic disruption like the COVID-19 pandemic. The research provides important guidelines for practitioners, indicating that organizations wanting to enhance their ESG practices should focus on building innovation capabilities rather than expansion diversification. For policymakers, the recommendations include designing incentive systems like tax credits for R&D, mandatory ESG disclosures, and green purchasing criteria that support innovative governance-based strategies. The SSEF that has been proved valid offers a tool for diagnosis that can be utilized by boards and strategic groups in their annual strategic reviews. Future research must build on SSEF in order to conduct experiments with longitudinal designs to improve causal attribution. Future research could further explore comparative studies on how strategic decisions interact in different national contexts such as regulatory regimes, cultural values, and capital market structures. The use of AI-enabled strategic analytics provides an exciting new front for measuring the sustainability performance in real time. The development of sectoral SSEFs related to energy transition, agri-food, and health is an area of high potential value for research. Another topic that could yield interesting findings is the involvement of stakeholders in developing strategic sustainability.
